## **ABSTRAK**

Gagal ginjal Kronis adalah kondisi yang terjadinya penurunan fungsi ginjal dalam mempertahankan keseimbangan didalam tubuh. Hilangnya fungsi ginjal membuat seseorang memerlukan terapi pengganti ginjal yaitu hemodialisa. Terapi hemodialisa yang dilakukan dalam jangka panjang menyebabkan keletihan. Keletihan dapat diatasi menggunakan terapi *Progressive Muscle Relaxtation* yang dapat membuat seseorang menjadi lebih rileks dan menurunkan keletihan. Tujuan penulisan Karya Ilmiah Ners ini yaitu untuk menganalisis terapi *Progressive Muscle Relaxtation* sebagai *evidence based practice* pada pasien gagal ginjal kronis yang menjalani hemodialisa untuk menurunkan keletihan. Prosedur yang dilakukan untuk asuhan keperawatan dimulai dengan pengkajian, diagnosa, intervensi, implementasi dan evaluasi keperawatan. Diagnosa yang muncul pada Ny. H yaitu hipervolemia, perfusi perifer tidak efektif, defisit nutrisi dan Keletihan. Untuk mengatasi keletihan dengan dilakukan teknik *Progressive Muscle Relaxtation* (PMR) sebelum dilakukan *Progressive Muscle Relaxtation* Ny. H mengatakan letih setelah melakukan hemodialisa. Setelah dilakukan *Progressive Muscle Relaxtation* letih berkurang. Diharapkan terapi *Progressive Muscle Relaxtation* (PMR) dapat dijadikan sebagai intervensi keperawatan untuk menurunkan keletihan pada pasien gagal ginjal kronis yang akan menjalani hemodialisa.

**ABSTRACT**

Chronic kidney failure is a condition where there is a decrease in kidney function in maintaining balance in the body. Loss of kidney function makes a person need kidney replacement therapy, namely hemodialysis. Hemodialysis therapy carried out in the long term causes fatigue. Fatigue can be overcome by using Progressive Muscle Relaxation therapy which can make a person more relaxed and reduce fatigue. The purpose of writing this Scientific Work on Nurses is to analyze Progressive Muscle Relaxation therapy as an evidence based practice in chronic kidney failure patients undergoing hemodialysis to reduce fatigue. The procedures carried out for nursing begin with assessment, diagnosis, intervention, implementation and evaluation of clots. The diagnosis that emerged in Mrs. H is hypervolemia, ineffective peripheral perfusion, nutritional deficits and fatigue. To overcome fatigue by doing the Progressive Muscle Relaxation (PMR) technique before doing Progressive Muscle Relaxation Mrs. H said he was tired after doing hemodialysis. After doing Progressive Muscle Relaxation, fatigue decreases. It is estimated that Progressive Muscle Relaxation (PMR) therapy can be used as a clotting intervention to reduce fatigue in patients with chronic kidney failure who will undergo hemodialysis.
